Together with colleagues at the Max Planck Institute for the Physics of Complex Systems in Dresden, Germany, and the Universities of Geneva and Queensland, Australia, researchers at Delft University of Technology have created the first four qubits of a 'universal' quantum computer. Scientists use qubits to represent a variable, or 'state' of a system. If a qubit is 0, the system exists in one particular state, if a qubit is 1, it exists in another state. If a single qubit exists in its 1 state, it represents a binary number, and a qubit in the 0 state represents a binary number with a 1 in the position that the first qubit is in its 1 state. Unlike a classical computer that stores information in 'bits', a quantum computer stores information in qubits. This allows for numbers that would be too complex to store on a classical computer to be represented as a number of qubits instead. Using qubits also means that the systems can work on problems that would be too complex for a classical computer to handle. The new quantum computer consists of four qubits that are capable of simulating 64 qubits. Sangtae Moon, a scientist at Delft University of Technology, said the new quantum computer was much more powerful than the previous quantum computers and would also provide useful tools for studying quantum mechanics and quantum computing. "The full 64 qubits can be built by a large number of four-qubit sets," Moon said. "So the biggest possible quantum computer can be built from the small quantum computer by assembling a few four-qubit sets. "This small quantum computer can simulate the 64-qubit quantum computer which is much larger than any other existing quantum computer. "And for quantum information processing, it is easy to use the small quantum computer to evaluate large complex numbers that would be too difficult to compute 82157476af
